

THE DYNAMICAL MORDELL-LANG PROBLEM

J. P. BELL, D. GHIOCA, AND T. J. TUCKER

ABSTRACT. Let X be a Noetherian space, let $\Phi : X \rightarrow X$ be a continuous function, let $Y \subseteq X$ be a closed set, and let $x \in X$. We show that the set $S := \{n \in \mathbb{N} : \Phi^n(x) \in Y\}$ is a union of at most finitely many arithmetic progressions along with a set of Banach density zero. In particular, we obtain that given any quasi-projective variety X , any rational map $\Phi : X \rightarrow X$, any subvariety $Y \subseteq X$, and any point $x \in X$ whose orbit under Φ is in the domain of definition for Φ , the set S is a finite union of arithmetic progressions together with a set of Banach density zero. We prove a similar result for the backward orbit of a point.

1. INTRODUCTION

The classical Mordell-Lang question (solved by Faltings [9] in the case of abelian varieties and by Vojta [19] in the case of semiabelian varieties) asks for a description of the algebraic relations between points in a given finitely generated subgroup of a semiabelian variety G defined over \mathbb{C} . More precisely, the Mordell-Lang problem asks that the intersection between any subvariety Y of G with a finitely generated subgroup Γ of $G(\mathbb{C})$ is a finite union of subgroups of Γ . Therefore, Faltings and Vojta's results assert that there exists a robust *Mordell-Lang principle* which governs the geometry of a semiabelian variety.

If we interpret Γ as the image of the identity $0 \in G(\mathbb{C})$ under a finitely generated subgroup of translations on G , then we obtain a reformulation of the Mordell-Lang question in the context of algebraic dynamics. One may further generalize and ask for a description of the intersection between any subvariety Y of G with the orbit of any point $\alpha \in G(\mathbb{C})$ under a finitely generated commutative semigroup S of endomorphisms of G . However, this generalization turns out to have surprising answers; in particular, if the endomorphisms from S are group homomorphisms, then the Mordell-Lang principle applies only if each endomorphism from S has diagonalizable Jacobian at the identity of G (see [14] for a full discussion of this problem). However, if we consider the case of a cyclic semigroup S , i.e. S is generated by a single endomorphism of G , then the Mordell-Lang principle holds for semiabelian varieties, and furthermore it is expected to hold in much higher generality. The following Conjecture was formulated in [11].

Conjecture 1.1. *Let X be any quasi-projective variety defined over \mathbb{C} , let Y be any subvariety of X , let $\alpha \in Y(\mathbb{C})$, and let Φ be an endomorphism of X . Then the set of $n \in \mathbb{N}$ such that $\Phi^n(\alpha) \in Y(\mathbb{C})$ is a finite union of arithmetic progressions.*

We note that for an arithmetic progression we allow the possibility that its ratio equals 0 (in which case it is constant); so, in Conjecture 1.1 we allow the possibility of a finite intersection (which often is the case). Also we denote by $\mathcal{O}_\Phi(\alpha)$ the orbit of α under Φ , i.e. the set consisting of all $\Phi^n(\alpha)$ for nonnegative integers n (as

always in algebraic dynamics, we denote by Φ^n the n -th iterate of Φ). In case of a rational self-map Φ we always work under the hypothesis that $\mathcal{O}_\Phi(\alpha)$ is entirely contained in the domain of definition for Φ .

A reformulation of Conjecture 1.1 would be that if Y is a subvariety of X which contains infinitely many points of the form $\Phi^n(\alpha)$ (with $n \in \mathbb{N}$), then Y must contain a positive dimensional periodic subvariety under the action of Φ , which has nontrivial intersection with $\mathcal{O}_\Phi(\alpha)$. This statement is in line with the classical Mordell-Lang problem, since in that case, if a subvariety Y of a semiabelian variety contains infinitely many points from a finitely generated subgroup Γ , then Y must contain a translate of an algebraic subgroup of positive dimension which has nontrivial intersection with Γ .

Conjecture 1.1 was proved in [2] for all étale endomorphisms Φ of any quasi-projective variety X . The proof relies on constructing a p -adic analytic function which parametrizes the orbit of α under Φ . This idea was pioneered by one of the authors in [1] (see also [3] for an extension of this method to orbits of subvarieties under an automorphism of an affine variety). We also note a similar construction of a v -adic parametrization for orbits of points under Drinfeld modules (done by two of the authors in [10]). A crucial ingredient in constructing this p -adic analytic map is the fact that the orbit does not intersect the ramified locus for Φ . However, the case of ramified self-maps Φ remains open in general. Only special instances of Conjecture 1.1 when the map Φ is ramified are known (see [5, 6, 13, 21] and also Wang [20] for an extension of the Dynamical Mordell-Lang problem to analytic endomorphisms of the unit disk). In almost all known ramified cases, Φ is given by the coordinatewise action through one-variable rational maps on $(\mathbb{P}^1)^m$, i.e. $\Phi(x_1, \dots, x_m) = (\varphi_1(x_1), \dots, \varphi_m(x_m))$ for some rational maps φ_i . In particular, very little is known for arbitrary endomorphisms of quasi-projective varieties, besides the result of Fakhruddin [8], who proved that the Dynamical Mordell-Lang Conjecture holds for *generic* endomorphisms of \mathbb{P}^n . In this paper we obtain a very general result for Noetherian spaces in support of Conjecture 1.1. First we recall the definition of Banach density for subsets of \mathbb{N} , and then we define Noetherian topological spaces.

Definition 1.2. Let S be a subset of the natural numbers. We define the *Banach density* of S to be

$$\delta(S) := \limsup_{|I| \rightarrow \infty} \frac{|S \cap I|}{|I|},$$

where the lim sup is taken over intervals I in the natural numbers. We say that a subset S of the natural numbers has *Banach density zero* if $\delta(S) = 0$.

Definition 1.3. Let X be a topological space. We say that X is *Noetherian* if it satisfies the descending chain condition for its closed subsets, i.e., there exists no infinite descending chain of proper closed subsets.

Theorem 1.4. *Let X be a Noetherian topological space, and let $\Phi : X \rightarrow X$ be a continuous function. Then for each $x \in X$ and for each closed subset Y of X , the set $S := \{n \in \mathbb{N} : \Phi^n(x) \in Y\}$ is a union of at most finitely many arithmetic progressions along with a set of Banach density zero.*

In particular, Theorem 1.4 implies the following Corollary which provides evidence to an extension of the Dynamical Mordell-Lang Conjecture to the case of rational maps.

Corollary 1.5. *Let X be a quasi-projective variety defined over a field K , let $\Phi : X \rightarrow X$ be a rational map defined over K , let $x \in X(K)$ such that $\mathcal{O}_\Phi(x)$ is contained in the domain of definition for Φ , and let Y be a K -subvariety of X . Then the set $S := \{n : \Phi^n(x) \in Y(K)\}$ is a union of at most finitely many arithmetic progressions along with a set of Banach density zero.*

Theorem 1.4 yields that the *Dynamical Mordell-Lang principle* almost holds for all continuous self-maps on Noetherian topological spaces. But obviously in this great generality it cannot always hold; we already know that if X is a p -adic analytic manifold and Φ is an analytic homomorphism, then the set S might be infinite without containing an infinite arithmetic progression (see [4, Proposition 7.1]). Theorem 1.4 shows that once removing finitely many arithmetic progressions contained in S , we obtain a very sparse set. The key for our proof is the following Proposition which we state in the context of endomorphisms of quasi-projective varieties, but it is true in the more general context of continuous maps on Noetherian spaces (see Proposition 3.1).

Proposition 1.6. *Let X be a quasi-projective variety defined over the field K , let $x \in X(K)$, and let $\Phi : X \rightarrow X$ be an endomorphism defined over K . Assume Y is a Zariski closed subset of X with the property that the set $S := \{n : \Phi^n(x) \in Y\}$ has positive Banach density. Then S contains an infinite arithmetic progression.*

Similar, but weaker, results were previously obtained in [7] and [4]. Denis [7] has treated the question of the distribution of the set S when Y does not contain a periodic subvariety. He showed, for any morphism of varieties over a field of characteristic 0, that S cannot be *very dense of order 2* (see [7, Définition 2]); this is a weaker conclusion than being of Banach density 0 (which is the result of our Proposition 1.6). On the other hand, the result of [4] yields a stronger statement in terms of the sparseness of the set S (assuming this set does not contain an infinite arithmetic progression); however the result of [4] applies only to endomorphisms of $(\mathbb{P}^1)^n$ of the form $(\varphi_1, \dots, \varphi_n)$ where each φ_i is a rational map defined over a field of characteristic 0.

We note that due to the general setting of our Theorem 1.4 we are able to prove Corollary 1.5 for all rational maps on a quasi-projective variety, as opposed to regular maps only. We also note that our results apply in positive characteristic, in which case one knows that the Dynamical Mordell-Lang Conjecture fails (since also the classical Mordell-Lang principle fails in positive characteristic). For example, if G is a semiabelian variety defined over \mathbb{F}_p , $C \subset G$ is a curve of genus greater than 1 defined over \mathbb{F}_p , and $\gamma \in C$ is a (generic) point not defined over $\overline{\mathbb{F}}_p$, then the intersection of C with the cyclic subgroup of G generated by γ consists of all points of the form $p^n \gamma$ for nonnegative integers n . So, in positive characteristic, Proposition 1.6 is (in some sense) best possible because the set S might consist of all powers of the prime number p only. We note that when K has positive characteristic, Ghioca and Scanlon conjectured the precise form of a set S from Proposition 3.1 (in case it does not contain an infinite arithmetic progression). It is expected in that case S consists of finitely many sets of the form

$$(1.6.1) \quad \left\{ \sum_{i=1}^k c_i p^{\ell_i n_i} : n_i \in \mathbb{N} \right\}$$

for given $k \in \mathbb{N}$, $c_i \in \mathbb{Q}$ and $\ell_i \in \mathbb{N}$. For example, let C be a curve of high genus (at least equal to 3) defined over \mathbb{F}_p embedded in its Jacobian J , and let $\alpha \in C(\mathbb{F}_p(t)) \setminus C(\mathbb{F}_p)$. Then the Zariski closure V of $C + C$ (where the addition takes place inside J) *generically* does not contain a translate of a positive dimensional algebraic group. So, the intersection of V with the orbit of $0 \in J$ under the translation-by- α map consists of points of the form $(p^m + p^n) \cdot \alpha$ only. In conclusion, if Φ is an endomorphism of a quasi-projective variety, assuming the set S from Proposition 1.6 does not contain an infinite arithmetic progression, if K has characteristic 0, then it is expected (according to Conjecture 1.1) that S is finite, while if K has positive characteristic, then it is expected to consist of finitely many subsets of the form (1.6.1). However, proving both these two precise results seems very difficult at this moment.

Using a similar approach to that of Theorem 1.4 we are able to prove a result similar to Theorem 1.4 for the backward orbit of a point in a Noetherian space. More precisely, for a Noetherian space X , a continuous function $f : X \rightarrow X$, and a point $x \in X$, we define a *coherent backward orbit* of x (with respect to f) be a sequence $\{x_{-n}\}_{n \geq 0}$ such that

$$x_0 = x \text{ and } f(x_{-n-1}) = x_{-n} \text{ for each } n \geq 0.$$

We obtain the following result.

Theorem 1.7. *Let X be a Noetherian space, let $f : X \rightarrow X$ be a continuous function, let $\{x_{-n}\}_{n \geq 0}$ be a coherent backward orbit of a point $x \in X$, and let $Y \subseteq X$ be a closed set. Then the set $S := \{n \in \mathbb{N} : x_{-n} \in Y\}$ is a union of at most finitely many arithmetic progressions and a set of Banach density zero.*

In particular, we ask the following question for algebraic dynamical systems.

Question 1.8. *Let X be a quasi-projective variety defined over \mathbb{C} , let $\Phi : X \rightarrow X$ be an endomorphism, let $\{x_{-n}\}_{n \geq 0}$ be a coherent backward orbit of a point $x \in X(\mathbb{C})$ (with respect to Φ), and let $Y \subseteq X$ be a subvariety. Is the set $S := \{n \in \mathbb{N} : x_{-n} \in Y(\mathbb{C})\}$ a union of at most finitely many arithmetic progressions?*

Question 1.8 is related to the Dynamical Manin-Mumford Conjecture (see [22, 12]). A positive answer to Question 1.8 yields that if a subvariety Y contains a Zariski dense set of points in common with a coherent backward orbit of a point $x \in X(\mathbb{C})$, then Y is periodic under the action of Φ . In the original formulation (see [22]) of the Dynamical Manin-Mumford Conjecture, it was asked whether a subvariety Y of a projective variety X would have to be preperiodic under the action of a polarizable endomorphism Φ of X if Y contains a Zariski dense set of preperiodic points (we call a point $y \in X$ preperiodic if its orbit $\mathcal{O}_\Phi(y)$ is finite). If the point x in Question 1.8 is preperiodic, then each point in a coherent backward orbit of x is preperiodic, and thus a positive answer to Question 1.8 provides a positive answer to this special case of the Dynamical Manin-Mumford Conjecture. We note that there are counterexamples coming from endomorphisms of CM abelian varieties to the original formulation of the Dynamical Manin-Mumford Conjecture (see [12, 17]), but we do not know whether those types of counterexamples can be found to Question 1.8.

While writing this paper we found out that, using different techniques, Clayton Petsche proved Theorem 1.4 when Φ is an endomorphism of an affine variety X . Petsche uses methods from topological dynamics and ergodic theory; in particular,

he uses Berkovich spaces and a strong topological version of the Poincaré Recurrence Theorem. Also, William Gignac indicated to us that both Theorem 1.4 and 1.7 follow using arguments stemming from a deep result of ergodic theory on Noetherian spaces proven by Charles Favre (this is Théorème 2.5.8 in Favre's PhD thesis); see also [16, Theorem 1.6] for an alternative proof of Favre's result using measure-theoretic arguments. We thank both Clayton Petsche and William Gignac for useful conversations on this topic. An advantage of our direct approach to proving Theorem 1.4 (and the related results) is that we derive a simple result regarding subsets of \mathbb{N} of positive Banach density (see Lemma 2.1) which allows us to derive concrete quantitative results (see Theorem 4.1 and also Remark 4.2).

We now briefly sketch the plan of this paper. In Section 2, we prove the key technical Lemma 2.1. In Section 3 we prove Proposition 3.1 (which is essentially Proposition 1.6 for Noetherian spaces) and then deduce various consequences such as Theorems 1.4 and 1.7. We conclude with some remarks on quantitative results, including Theorem 4.1 in Section 4.

2. A TECHNICAL LEMMA

The key result for the proof of Proposition 1.6 and its related consequences is the following Lemma.

Lemma 2.1. *Let S be a set of positive integers having positive Banach density. Let $N = \lceil 1/\delta(S) \rceil + 1$, where $\lceil x \rceil$ as usual denotes the greatest integer less than or equal to x . Then there is a positive integer k and a subset $Q \subseteq S$ such that*

- (i) $k \leq N - 1$;
- (ii) $\delta(Q) \geq \frac{N\delta(S)-1}{2N^2(N-1)} > 0$; and
- (iii) for all $a \in Q$, we have $a + k \in S$.

Proof. By assumption, $\frac{1}{N} < \delta(S)$. So there exist intervals I_n with $|I_n| \rightarrow \infty$ such that

$$\frac{|S \cap I_n|}{|I_n|} > \frac{\delta(S) + \frac{1}{N}}{2}.$$

Let $P = \{i: |\{iN + 1, \dots, (i+1)N\} \cap S| \geq 2\}$. We claim that P has positive Banach density. To see this, let $J_n = \{i: \{iN + 1, \dots, (i+1)N\} \subseteq I_n\}$. Then $|J_n| \leq \frac{|I_n|}{N}$ and $|J_n| \rightarrow \infty$ as $n \rightarrow \infty$. For $i \in J_n \setminus P$ we have $S \cap \{iN + 1, \dots, (i+1)N\}$ has size at most 1 and for $i \in P \cap J_n$ we have $S \cap \{iN + 1, \dots, (i+1)N\}$ has size at most N . Since there are at most $2N$ elements of I_n that are not accounted for by taking the union of the $\{iN + 1, \dots, (i+1)N\}$ with $i \in J_n$, we see that

$$\frac{(\delta(S) + \frac{1}{N}) \cdot |I_n|}{2} \leq |I_n \cap S| \leq |J_n \setminus P| + N|P \cap J_n| + 2N.$$

Using the fact that $|J_n| \leq \frac{|I_n|}{N}$, we see

$$\frac{(\delta(S) + \frac{1}{N}) \cdot N|J_n|}{2} \leq |J_n \setminus P| + N|P \cap J_n| + 2N.$$

Dividing by $N|J_n|$ now gives

$$\frac{\delta(S) + \frac{1}{N}}{2} \leq \frac{|J_n \setminus P|}{N|J_n|} + \frac{|P \cap J_n|}{|J_n|} + \frac{2}{|J_n|}.$$

Since $|J_n \setminus P| \leq |J_n|$, we get

$$\frac{\delta(S) + \frac{1}{N}}{2} \leq \frac{1}{N} + \frac{|P \cap J_n|}{|J_n|} + \frac{2}{|J_n|},$$

which gives

$$\frac{\delta(S) - \frac{1}{N}}{2} \leq \frac{|P \cap J_n|}{|J_n|} + \frac{2}{|J_n|}.$$

Since $|J_n| \rightarrow \infty$, we see that $\delta(P) \geq \frac{\delta(S) - \frac{1}{N}}{2}$.

For each $i \in P$, we pick $a_i, b_i \in \{iN+1, \dots, (i+1)N\} \cap S$ with $0 < b_i - a_i < N$. For $j \in \{1, \dots, N-1\}$, we let $P_j := \{i \in P : b_i - a_i = j\}$. Then $P = \bigcup_{j=1}^{N-1} P_j$ and since Banach density is subadditive, we have

$$\delta(P) \leq \sum_{j=1}^{N-1} \delta(P_j).$$

Thus there is some $k \in \{1, \dots, N-1\}$ such that $\delta(P_k) \geq \frac{\delta(P)}{N-1}$. Let $Q := \{a_i : i \in P_k\} \subseteq S$. Then $a + k \in S$ for all $a \in Q$ and a simple computation yields

$$\delta(Q) \geq \frac{\delta(P_k)}{N} \geq \frac{N\delta(S) - 1}{2N^2(N-1)} > 0,$$

as desired. \square

We find useful (see Remark 4.2) stating the following Corollary of Lemma 2.1.

Corollary 2.2. *Let S be a set of positive integers having positive Banach density. Then there is a positive integer $k < \frac{2}{\delta(S)}$ and a subset $Q \subseteq S$ such that*

- (a) $\delta(Q) \geq \frac{\delta(S)^3}{24}$; and
- (b) for all $a \in Q$, we have $a + k \in S$.

Proof. We let $\delta := \delta(S)$, and we apply Lemma 2.1 with $N = \lceil \frac{2}{\delta} \rceil$ (which is at least equal to $\lceil \frac{1}{\delta} \rceil + 1$ since $\delta \leq 1$). This shows the existence of a set $Q \subseteq S$ satisfying property (b) above; in addition $\delta(Q) \geq \frac{N\delta-1}{2N^2(N-1)}$. So, in order to show that (a) holds, it suffices to prove that $\frac{N\delta-1}{2N^2(N-1)} \geq \frac{\delta^3}{24}$, which is equivalent with proving that

$$\frac{N\delta-1}{N-1} \geq \frac{N^2\delta^3}{12} = \frac{2}{3N} \cdot \left(\frac{N\delta}{2}\right)^3.$$

Since $N = \lceil \frac{2}{\delta} \rceil \leq \frac{2}{\delta}$, then it suffices to show that $\frac{N\delta-1}{N-1} \geq \frac{2}{3N}$, which is equivalent with showing that

$$(2.2.1) \quad \delta \geq \frac{5}{3N} - \frac{2}{3N^2}.$$

Because $N = \lceil \frac{2}{\delta} \rceil$, then $\frac{2}{\delta} < N+1$ and so, $\delta > \frac{2}{N+1}$. Then inequality (2.2.1) follows since

$$(2.2.2) \quad \frac{2}{N+1} - \left(\frac{5}{3N} - \frac{2}{3N^2}\right) = \frac{N-5}{3N(N+1)} + \frac{2}{3N^2} \geq 0.$$

Inequality 2.2.2 is obvious for all $N \geq 5$, while for $N \in \{2, 3, 4\}$ the inequality can be checked directly (note that $N = \lceil \frac{2}{\delta} \rceil \geq 2$ because $\delta \leq 1$). \square

3. PROOF OF OUR MAIN RESULTS

Theorem 1.4 will follow as a consequence of the following Proposition which is a generalization of Proposition 1.6.

Proposition 3.1. *Let X be a Noetherian topological space, let $\Phi : X \rightarrow X$ be a continuous map, let $x \in X$, let Y be a closed subset of X , and let $S := \{n : \Phi^n(x) \in Y\}$. If S has positive Banach density, then it contains an infinite arithmetic progression.*

Proof. Consider the set \mathcal{V} of all closed subsets V of X with the property that $T_V := \{n : \Phi^n(x) \in V\}$ has positive Banach density but does not contain an infinite arithmetic progression. If \mathcal{V} is empty, then there is nothing to prove. Thus we may assume, towards a contradiction, that \mathcal{V} is non-empty. We let W be a minimal element of \mathcal{V} with respect to the inclusion of sets (note that such an element exists since X is Noetherian). By Lemma 2.1, we have a positive integer k and a subset $Q \subseteq T_W$ with $\delta(Q) > 0$ such that $a + k \in T_W$ for all $a \in Q$.

If $n \in Q$, then $\Phi^n(x) \in W$ and $\Phi^{n+k}(x) \in W$. Thus $\Phi^n(x) \in W \cap \Phi^{-k}(W)$ whenever $n \in Q$. If $\Phi^{-k}(W) \supsetneq W$ then T_W has the property that $n + k \in T_W$ whenever $n \in T_W$ and since T_W is non-empty, it contains an infinite arithmetic progression, which contradicts the fact that $W \in \mathcal{V}$. Thus $Z := W \cap \Phi^{-k}(W)$ is a proper closed subset of W (since Φ is continuous and W is closed) and so we have $\Phi^n(x) \in Z$ for all $n \in Q$. Since Q has positive Banach density, we obtain that $T_Z \supseteq Q$ also has positive Banach density and therefore T_Z contains an infinite arithmetic progression. Since $T_Z \subseteq T_W$, we see that T_W contains an infinite arithmetic progression, a contradiction. This concludes our proof. \square

Theorem 1.4 follows easily now.

Proof of Theorem 1.4. Suppose not. Let \mathcal{V} be the collection of all closed subsets V of X that have the property that there is some continuous map $g : V \rightarrow V$, and some closed subset W of V , and a point $y \in V$ such that $\{n : g^n(y) \in W\}$ cannot be expressed as a finite union of arithmetic progressions along with a set of Banach density zero.

By assumption, $X \in \mathcal{V}$ and so we may choose a minimal element $V \in \mathcal{V}$. Then there is some continuous map $g : V \rightarrow V$, some closed subset W of V , and some point $y \in V$ such that $T := \{n : g^n(y) \in W\}$ cannot be expressed as a finite union of arithmetic progressions along with a set of Banach density zero. We necessarily have that $W_i := g^{-i}(W)$ is a proper closed subset of V (note that g is continuous), since otherwise T would contain every integer greater than or equal to i (and thus it would be the union of an arithmetic progression with a finite set). Moreover, by our choice of V , W and y , it follows that $\delta(T) > 0$ and thus by Proposition 3.1, there exist $a, b \in \mathbb{N}$ such that $T \supseteq \{an + b : n \geq 0\}$. Let C_i denote the closure of $S_i := \{g^{(an+b)}(y) : n \geq i\}$. Then

$$C_0 \supseteq C_1 \supseteq \cdots$$

is a descending chain of closed sets and hence there is some m such that $C_m = C_{m+1} = \cdots$. We take $V_0 = C_m$. Then $g^{-a}(V_0) \supseteq g^{-a}(S_{m+1}) \supseteq S_m$ and since $g^{-a}(V_0)$ is closed we thus see it contains the closure of S_m , which is V_0 .

Then $V_0 \subseteq W$ and we have $g^{-a}(V_0) \supseteq V_0$. We let V_j denote the closed set $g^{-j}(V_0)$ for $j \in \{1, \dots, a-1\}$. Since $V_j \subseteq W_{a+j} \subsetneq V$, we see that each V_j is a

proper subset for $0 \leq j \leq a-1$. Then $g^{-a}(V_j) = g^{-a}(g^{-j}(V_0)) = g^{-j}(g^{-a}(V_0)) \supseteq g^{-j}(V_0) = V_j$, and so for $j \in \{0, \dots, a-1\}$, we have $g^{-j+na+b}(y) \in V_j$ for every $n > m$. Moreover, since $g^{-a}(V_j) \supseteq V_j$, we have that $h := g^a$ restricts to continuous maps $h : V_j \rightarrow V_j$ for each $0 \leq j \leq a-1$. We let $y_j := g^{-j+a+b}(y)$. It follows from the minimality of V that

$$T_j := \{n \geq m : h^n(y_j) \in W \cap V_j\}$$

is a finite union of arithmetic progressions along with a set of Banach density zero. On the other hand,

$$T_j = \{n \geq m : g^{-j+a(n+1)+b}(y) \in W\},$$

for each $j = 0, \dots, a-1$. Then, up to a finite set, we have

$$T = \bigcup_{j=0}^{a-1} (aT_j + b + a - j),$$

where for any set $U \subseteq \mathbb{N}$ and any $c \in \mathbb{N}$, we let $c \cdot U$ be the set $\{cj : j \in U\}$, and we let $c + U := U + c$ be the set $\{c + j : j \in U\}$. Hence T is a finite union of arithmetic progressions along with a set of Banach density zero. \square

As a consequence to our main result, we can prove the following (seemingly) stronger statement.

Theorem 3.2. *Let X be a Noetherian space, let $U \subseteq X$ be an open subset, and let $\Phi : U \rightarrow X$ be a continuous map. Let $x \in X$ such that $\Phi^n(x) \in U$ for each nonnegative integer n . Then for each closed set $Y \subseteq X$, the set $S := \{n \in \mathbb{N} : \Phi^n(x) \in Y\}$ is a union of at most finitely many arithmetic progressions along with a set of Banach density zero*

Proof. Let $Z := \bigcap_{n \geq 0} \Phi^{-n}(U)$; we know that Z is nonempty since x (and therefore $\mathcal{O}_\Phi(x)$) is contained in Z . We endow Z with the inherited topology from X ; then Z is also a Noetherian space. Furthermore, by its definition, we obtain that Φ restricts to a self-map $\Phi_Z : Z \rightarrow Z$. Next we show that Φ_Z is continuous.

Indeed, let $V \subseteq X$ be an open set and we need to show that $\Phi_Z^{-1}(V \cap Z)$ is open in Z . This follows immediately once we prove that $\Phi_Z^{-1}(V \cap Z) = \Phi^{-1}(V) \cap Z$ because $\Phi : U \rightarrow X$ is continuous and so $\Phi^{-1}(V)$ is open in U and (because U is an open subset of X) it is also open in X which yields that $\Phi^{-1}(V) \cap Z$ is open in Z . To see that $\Phi_Z^{-1}(V \cap Z) = \Phi^{-1}(V) \cap Z$ we note that for each $y \in \Phi_Z^{-1}(V \cap Z) \subseteq Z$ we have $\Phi_Z(y) \in V$. So, $\Phi(y) \in V$ and thus $y \in \Phi^{-1}(V) \cap Z$. Conversely, if $y \in \Phi^{-1}(V) \cap Z$, then $y \in Z$ and so $\Phi_Z(y) \in V \cap Z$ as claimed.

Therefore $\Phi_Z : Z \rightarrow Z$ is a continuous map on a Noetherian space. Hence by Theorem 1.4, the set of all $n \in \mathbb{N}$ such that $\Phi_Z^n(x) \in Y \cap Z$ is a union of at most finitely many arithmetic progressions along with a set of Banach density zero. Because $\Phi = \Phi_Z$ on Z then $\Phi^n(x) \in Y$ if and only if $\Phi_Z^n(x) \in Y \cap Z$, which concludes our proof. \square

Corollary 1.5 is an immediate consequence of Theorem 3.2. The proof for Theorem 1.7 is similar to the proof of Theorem 1.4 and it relies on the following result.

Proposition 3.3. *Let X be a Noetherian space, let $f : X \rightarrow X$ be a continuous function, let $\{x_{-n}\}_{n \geq 0}$ be a coherent backward orbit of a point $x \in X$, and let*

$Y \subseteq X$ be a closed set. If the set $S := \{n \in \mathbb{N} : x_{-n} \in Y\}$ has positive Banach density then it contains an infinite arithmetic progression.

Proof. The proof is similar to the proof of Proposition 3.3. Consider the set \mathcal{V} of all closed subsets V of X with the property that $T_V := \{n : x_{-n} \in V\}$ has positive Banach density but does not contain an infinite arithmetic progression. If \mathcal{V} is empty, then there is nothing to prove. Thus we may assume, towards a contradiction, that \mathcal{V} is non-empty. We let W be a minimal element of \mathcal{V} with respect to the inclusion of sets (note that such an element exists since X is Noetherian). By Lemma 2.1, we see that there exists a positive integer k and a set $Q \subseteq T_W$ of positive Banach density such that if $n \in Q$ then $n+k \in T_W$. Thus $x_{-n-k} \in W \cap f^{-k}(W)$ whenever $n \in Q$. There are two cases: either $f^{-k}(W) \supseteq W$ or not.

Assume now that $f^{-k}(W) \supseteq W$; so if $y \in W$, then also $f^k(y) \in W$. Then T_W has the property that $n-k \in T_W$ whenever $n \in T_W$ and $n \geq k$. Because Q has positive Banach density, then it is infinite, and therefore there exists $j \in \{0, \dots, k-1\}$ such that there exist infinitely many $n \in Q$ satisfying $n \equiv j \pmod{k}$. So there exists a sequence of integers $n_i \rightarrow \infty$ contained in T_W such that $n_i \equiv j \pmod{k}$ for each i and moreover, $n_i - \ell k \in T_W$ for all $\ell \geq 0$ such that $n_i - \ell k \geq 0$. Thus T_W contains the infinite arithmetic progression $\{j + \ell k\}_{\ell \geq 0}$, as desired.

Assume now that $W \not\subseteq f^{-k}(W)$. Then $Z := W \cap f^{-k}(W)$ is a proper closed subset of W and so we have $x_{-n-k} \in Z$ for all $n \in Q$. Since Q has positive Banach density, we obtain that also T_Z has positive Banach density (note that $\delta(Q+k) = \delta(Q) > 0$ and $(Q+k) \subseteq T_Z$). Hence T_Z contains an infinite arithmetic progression (because Z is a proper subset of W). Since $T_Z \subseteq T_W$, we see that T_W contains an infinite arithmetic progression, a contradiction. This concludes our proof. \square

Theorem 1.7 follows from Proposition 3.3 similar to the proof of Theorem 1.4.

Proof of Theorem 1.7. Let \mathcal{V} be the collection of all closed subsets V of X that have the property that there is some continuous map $g : V \rightarrow V$, and some closed subset W of V , and a coherent backward orbit $\{y_{-n}\}$ of a point $y \in V$ such that $\{n : y_{-n} \in W\}$ cannot be expressed as a finite union of arithmetic progressions along with a set of Banach density zero.

Assume, for contradiction, that $X \in \mathcal{V}$ and so we may choose a minimal element $V \in \mathcal{V}$. Then there is some continuous map $g : V \rightarrow V$, some closed subset W of V , and a coherent backward orbit $\{y_{-n}\}_{n \geq 0}$ of a point $y \in V$ such that $T := \{n : y_{-n} \in W\}$ cannot be expressed as a finite union of arithmetic progressions along with a set of Banach density zero.

For each $i \in \mathbb{N}$ we let $W_i := g^{-i}(W)$. We claim that if $W_i = V$ for some $i \in \mathbb{N}$, then T is a union of at most finitely many arithmetic progressions along with a finite set (which obviously has Banach density zero). Indeed, for each $j \in \{0, \dots, i-1\}$ we let $T_{i,j} := \{n \in T : n \equiv j \pmod{i}\}$. Then $T = \bigcup_{j=0}^{i-1} T_{i,j}$. Assume $T_{i,j}$ is infinite (for some $0 \leq j \leq i-1$). Since $W_i = V$ then for each $n \in T$ also $n-i \in T$ and therefore $n - i\ell \in T$ for all $\ell \geq 0$ such that $n - i\ell \geq 0$. Because we assumed that $T_{i,j}$ is infinite, then $j + i\ell \in T$ for all $\ell \geq 0$. In conclusion, T is indeed a union of at most finitely many arithmetic progressions (of ratio i) along with a finite set.

So from now on assume that $W_i := g^{-i}(W)$ is a proper closed subset of V (note that g is continuous). Moreover, by our choice of V , W and y , it follows that $\delta(T) > 0$ and thus by Proposition 3.3, there exist $a, b \in \mathbb{N}$ such that $T \supseteq \{an + b : n \geq 0\}$.

Let C_i denote the closure of $S_i := \{y_{-(an+b)} : n \geq i\}$. Then

$$C_0 \supseteq C_1 \supseteq \cdots$$

is a descending chain of closed sets and hence there is some m such that $C_m = C_{m+1} = \cdots$. We take $V_0 = C_m$. Then $g^{-a}(V_0) \supseteq g^{-a}(S_m) \supseteq S_{m+1}$ and since $g^{-a}(V_0)$ is closed we thus see it contains the closure of S_{m+1} , which is V_0 .

Then $V_0 \subseteq W$ is closed and we have $g^{-a}(V_0) \supseteq V_0$. We let V_j denote the closed set $g^{-j}(V_0)$ for $j \in \{1, \dots, a-1\}$. Since $V_j \subseteq W_{a+j} \subsetneq V$, we see that each V_j is a proper subset for $0 \leq j \leq a-1$. Then $g^{-a}(V_j) = g^{-a}(g^{-j}(V_0)) = g^{-j}(g^{-a}(V_0)) \supseteq g^{-j}(V_0) = V_j$, and so for $j \in \{0, \dots, a-1\}$, we have $y_{-(na+b+j)} \in V_j$ for every $n \geq m$. Moreover, since $g^{-a}(V_j) \supseteq V_j$, we have that $h := g^a$ restricts to continuous maps $h : V_j \rightarrow V_j$ for each $0 \leq j \leq a-1$. It follows from the minimality of V that

$$T_j := \{n \geq m : (y_{-(na+b+j)}) \in W \cap V_j\}$$

is a finite union of arithmetic progressions along with a set of Banach density zero (since $\{y_{-j-na-b}\}_{n \geq 0}$ is a coherent backward orbit of y_{-j-b} under the action of h). Then, up to a finite set, we have

$$T = \bigcup_{j=0}^{a-1} (aT_j + b + j)$$

and hence T is a finite union of arithmetic progressions along with a set of Banach density zero. \square

4. SOME QUANTITATIVE RESULTS

The following result is an easy application of Lemma 2.1.

Theorem 4.1. *Let X be a quasi-projective variety defined over a field K , let $\Phi : X \rightarrow X$ be an endomorphism defined over K , let $C \subseteq X$ be an irreducible curve, and let $\alpha \in X(K)$ be a point that is not preperiodic under Φ . If the set $S := \{n \in \mathbb{N} : \Phi^n(\alpha) \in C(K)\}$ has Banach density $\delta > 0$, then S contains an infinite arithmetic progression of ratio $k = \frac{1}{\delta}$, and $\Phi^k(C) \subseteq C$.*

Proof. It follows from Lemma 2.1 applied with $N = \lceil \frac{1}{\delta} \rceil + 1$ that there exists a positive integer $k \leq \lceil \frac{1}{\delta} \rceil$ and a subset $Q \subset S$ of positive density such that for each $n \in Q$, also $\Phi^{n+k}(\alpha) \in C(K)$. So $\Phi^n(\alpha) \in C \cap \Phi^{-k}(C)$. Hence, $C \cap \Phi^{-k}(C)$ contains an infinite set of points. Since C is an irreducible curve, we see then that $C \subseteq \Phi^{-k}(C)$; thus $\Phi^k(C) \subseteq C$. This yields the desired infinite arithmetic progression of ratio $k \leq \frac{1}{\delta}$. If $k < 1/\delta$, then the existence of this arithmetic progression would imply that $\delta \geq 1/k > \delta$, a contradiction. Thus, $k = \frac{1}{\delta}$. \square

Remark 4.2. Applying the technique of the proof of Theorem 4.1 recursively in the case of endomorphisms Φ of \mathbb{P}^n of degree m one can obtain a similar result for all projective irreducible subvarieties $V \subseteq \mathbb{P}^n$ of degree at most D and dimension at most e . More precisely, with the above geometric data m, D, e , for every $\delta > 0$ there exists a bound $M := M(\delta, m, D, e)$ such that if the set $S := \{n \in \mathbb{N} : \Phi^n(\alpha) \in V(K)\}$ has Banach density at least equal to δ , then S contains an infinite arithmetic progression of ratio at most M . One uses induction on the dimension e of V , with the base case being Theorem 4.1. Then with the use of Bézout's Theorem, one controls both the degrees and the number of the irreducible components of $V \cap \Phi^{-k}(V)$. We obtain $M(\delta, m, D, 1) = \frac{1}{\delta}$ (by Theorem 4.1), and then for $e \geq 2$ one

applies this technique coupled with Corollary 2.2 to derive the following recursive formula

$$M(\delta, m, D, e) = M\left(\frac{\delta^3}{24m^{\frac{2}{3}}D^2}, m, m^{\frac{2}{3}}D^2, e-1\right).$$
